A FLEXIBLE DATA BUFFER DISPLAY ROUTINE FOR LAB-8 SYSTEMS

DECUS Program Library Write-up

DECUS NO. 8-637

ABSTRACT

This set of five subroutines may be called to display the contents of a data buffer on the oscilloscope of an AX-08 (LAB-8) system. Software control of format as either a point or a histogram display, vertical scaling and placement in the two axes of the display is provided.

REQUIREMENTS

Storage - these subroutines occupy 162(8) storage locations and may be placed anywhere in memory on a single page.

Equipment - basic LAB-8 system with oscilloscope display.

USAGE

Loading - The subroutines are supplied as a PAL symbolic tape with no origin setting, but terminated with a PAUSE directive, which may be assembled to any convenient location.

Calling Sequence - The display subroutine is called by an effective JMS PLOTTER with the relevant parameters (detailed elsewhere) set by a user provided subroutine. As a call to the display generation subroutine will only display the data buffer a single time, multiple calls are required to provide the refreshing necessary for a visual display. Certain parameters are destroyed by the routine and must be reset between successive calls. It is expected that the reset routine will provide the facilities for changing display format and as this is likely to be program specific no routine is supplied. The vertical scale controlling subroutines are called by an effective JMS VSFMUL to increase the vertical scale or an effective JMS VSFDIV to decrease the vertical scale.

RESTRICTIONS

Hardware - The standard AX-08 display restriction applies, namely no display is possible during the interval between an ADCV and subsequent RADC instruction. The normal display problem of "wrap-around" on both axes also holds, therefore data must be kept in the relevant range for the display.

DESCRIPTION

The subroutine PLOTTER generates a display according to the parameters set in various locations when it is called as detailed below.

BUFFER is set to point to the first location in the data buffer to be displayed and NOPTS is set to minus the number of points in the buffer. XAXIS and BASELN set the position of the display in the X and Y axes. XAXIS should be set to the initial point on the screen where the display is to start. BASELN is added to every data point, after any scaling has been carried out, and is especially useful when generating histograms as the effective zero for the display may be moved to the bottom of the display screen (-377 octal). XSTEP controls the distance between successive points on the display face and obviously should be selected to prevent "wrap around" on the X-axis of the display. RBIN controls the form of the data display. If it is set to -1 then the data is displayed as individual points whereas if it is set to -2 or less then a histogram display will be generated with each bin being that number of display points wide (each point being XSTEP apart). It should be noted that if the first or last values in the data buffer are non-zero then the routine will not join the leading or trailing edges respectively to the effective zero as defined by BASELN. Time is saved by not displaying null data because the routine automatically generates a baseline across the display from XAXIS to XEND at effective zero by calling the routine BASLIN on entry. It is possible to ensure that no baseline is drawn by setting XAXIS to the same value as XEND before the call to PLOTTER.

SCALE1 and SCALE2 provide a capability for vertical scaling of the display data (without buffer modification) as defined by Table 1. The routines VSFMUL, VSFDIV and VSETUP provide a means of achieving each of these scaling factors under program

control. An effective JMS VSETUP with a cleared accumulator returns the vertical scaling factor (VSF) to 1 and calls to VSFMUL or VSFDIV vary this by multiplying or dividing the VSF by two respectively. The variable VVAL is used to hold an index of the current display VSF (see table 1). The routines VSFMUL and VSFDIV also contain automatic exits if they are called to yield an invalid VSF.

TABLE 1

SCALE1	SCALE2	SCALING FACTOR	VVAL
CLL RAL	CLL RAL	4	-2
* NOP	CLL RAL	2	-1
CLL RAL	NOP	2	-1
NOP	NOP	1	0
RAR	NOP	0.5	1
* NOP	RAR	0.5	1
RAR	RAR	0.25	2

* - not actually used by VSETUP.

All parameters may be varied under program control to generate different displays but in certain cases it would be better to ensure that parameters are only changed between successive calls of the display generator otherwise a specific pass of the display generator may give unspecified results, e.g. consider changing the buffer pointer and the number of points counter just before the end of a display pass which would obviously cause wrap around and certainly destroy the display until the next call. If parameters are being changed on the interrupt then it is best to arrange that a new call is issued to the routine and that the

3. The third part of the document is a letter from the President of the United States to the Congress, dated January 3, 1801. It is a very important document, as it is the first time that the President has addressed the Congress since the establishment of the office.	
4. The fourth part of the document is a letter from the President of the United States to the Congress, dated January 3, 1801. It is a very important document, as it is the first time that the President has addressed the Congress since the establishment of the office.	
5. The fifth part of the document is a letter from the President of the United States to the Congress, dated January 3, 1801. It is a very important document, as it is the first time that the President has addressed the Congress since the establishment of the office.	

2. The second part of the document is a letter from the President of the United States to the Congress, dated January 3, 1801. It is a very important document, as it is the first time that the President has addressed the Congress since the establishment of the office.

parameters are reset as necessary. Two examples follow of parameter values to set up given displays.

- (i) to generate a display of a signal average containing 400 points starting at 50 on the X-axis and with no correction factor for the data. Each point to be displayed at successive points on the display face. A baseline to be plotted at effective zero from 50 to 450 on display.

XAXIS,	0062	/ 50 decimal
XSTEP,	0001	/ successive points
BASELN,	0000	/ no corrective factor
XEND,	7075	/ - 451 decimal
RBIN,	7777	/ 1 display point/data point
BUFFER,	DATA	/ address of data buffer
NOPTS,	7160	/ - 400 decimal

- (ii) to generate a histogram display of 100 bins, each four points wide, with effective zero at the base of the display screen starting at location 50 on the X-axis, with a baseline stretching from 50 to 450 at effective zero.

XAXIS,	0062	/ 50 decimal
XSTEP,	0001	/ successive points
BASELN,	7401	/ - 377 (base of screen Y-axis value)
XEND,	7075	/ - 451 decimal
RBIN,	7774	/ 4 point wide bin for each data point
BUFFER,	DATA	
NOPTS,	7634	/ - 100 decimal

To convert (ii) to a point display with each point being displayed four points apart XSTEP should be set to 4 and RBIN to -1.

The attached listing is heavily commented and should prove self explanatory. (the routine is shown assembled starting at loc. 0200).
